a Biopsies form no natural clusters

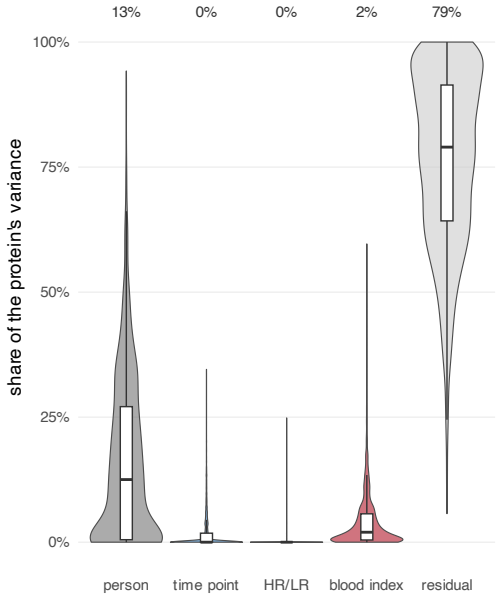

Correlation of 48 biopsies, blood-corrected, in average-linkage order; 16 people
Gap statistic, PAM on 10 PCs: k = 1

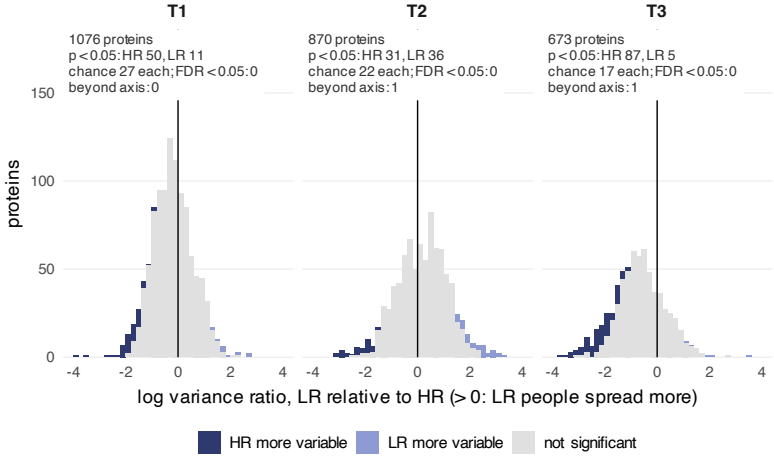

b Where the variance sits

variancePartition, 2,059 proteins; number: median share

c Does one group vary more? (exploratory)

DiffVar per time point, proteins observed in all 16 biopsies, 8 people per group

d What drives the main components

R^2 of each covariate alone; PC share of variance under its name

e Proteome at T2 and T3

As Figure 1b for the trained and post-bout levels; at both, the forced second cluster is S28's thin biopsy alone
